it's a powerful tool for photos and video. by working with images directly in your camera, you can use your skill as a photographer to automatically highlight and adjust the effects of the photos. you can apply special effects, including drift™, vintage, love, and much more. the details routinely record to memory, print and download on the olympus image share application, accessshare, or by using memorystick. not only can you control your data on any memory card or usb memory stick connected to the camera, such as sd, compact flash or compact flash type ii (cf), but also on pc or laptop. the system is compatible with d-mount lenses that are also compatible with the e-m1 mark iii (m42 and m42 x 1.0). at the moment, only compatible olympus lenses are also compatible with e-m1 mark iii. the new milc body mounts in the same orientation as the e-m5 mark ii. this gives photographers using existing lenses the ability to swap lenses between the e-m5 mark ii and the milc body, and vice versa. the equivalent focal lengths for the e-m5 mark iii are 28, 35, 50 and 100mm. the standard 10-stop-of-shutter-speed range extends up to 1/8000-second. the e-m5 mark iii can also utilize the time lapse mode feature of the e-m5 mk ii. exposing a raw file to a huge number of parameters is quite hard and one of the best ways to understand what a raw file looks like is to have at least two raw converters between you and your rawfile. this is one of the problems at the moment. no one has a clue what is in a raw file. this is much easier to see with sraw than a bayercoded raw file. sraws are deeper toned and more saturated. this is also sometimes called the "dirtiness effect". some people say that its because a mirrorlesscamera have small sensors. its not true. the reason a sraw looks more washed out is that a sraw is 23% more deep toned than a bayer raw file. this is because a bayer raw file has less information in each pixel. sraws are of course slower to process by a raw converter than a bayer raw file.

we use a leica el6000 stereo microscope for a detailed analysis of the skin biopsy. the magnified field of view of the microscope allows us to identify cells and structures in the biopsy that are not visible with the naked eye. this includes the various cell types such as keratinocytes, adipocytes, fibroblasts, melanocytes and melanophages (fig. 5 a–d), as well as the intercellular spaces, nuclei, nucleoli, epidermal islands, sebaceous glands and sweat glands (fig. 5 e–h). to determine if the thickening of the stratum corneum results in occlusion of these intercellular spaces, we measure the length and width of the intercellular spaces in our slides (fig. 6). we find that none of the intercellular spaces are occluded, indicating that they are either sealed tightly by desquamated cells or are filled by sebum. we observe no obvious abnormalities in the epidermis of the african elephants. although many parameters are altered in the arid environment that these animals live in, the thickness of the epidermis is similar to that found in adults loxodonta africana. this is consistent with a study that found that the epidermal thickness in mammals decreases with age and is about 10 times more thick when the animals are young than when adults are old (loxodonta africana in this

study). the thickness of loxodonta africana skin is similar to that found in adults belettis africana, suggesting that the biotype is a more representative b. africana for a b. africana. it's usually about four inches thick (b. 5ec8ef588b
